Analysing growth curves and other user-defined plates in opm

Lea A.I. Vaas Leibniz Institute DSMZ Markus Göker Leibniz Institute DSMZ

Abstract

This is tutorial about the analysis of growth curves and other user defined kinetics with the **opm** package in the version of December 19, 2013. It is explained how any kinds of growth or respiration measurements can be input into **opm**. We also show how Phenotype Microarray (PM) data with user-defined plate types can be analysed. Analysing such data visually and statistically requires in some cases adaptations of function arguments whose defaults are targeting PM data. All these practically relevant issues are explained in detail.

Keywords: Growth Kinetics.

1. Introduction

A detailed description of the OmniLog® Phenotype Microarray (PM) system, its measuring procedure and data characteristics are found in the vignette "opm: An R Package for Analysing OmniLog® Phenotype Microarray Data" (called "main tutorial" in the following). How substrate information stored within opm can be accessed and used for advanced visual and statistical analyses is explained in the vignette "Working with substrate information in opm" (called "substrate tutorial" in the following). The description of the methods below presupposes that the user is familiar with the usage of opm and has studied the main tutorial, the substrate tutorial as well as the entries of the opm manual relevant to her or his research. Especially the concepts behind, and the methods available for, the different classes of opm objects should be known before starting with this tutorial.

In addition to visual inspection or statistical comparative analyses of PM data, as described in the main tutorial and the substrate tutorial, users might be interested in analysing data other than PM data, or analysing PM with user-defined plate types. To work with user-defined PM plates only requires registering these plates, i.e. storing a mapping from well coordinates to substrate names, and optionally also a full, descriptive name for the plate. The analysis of data other than PM data, such as growth curves, additionally requires inputting these data and converting them to OPMX objects. Moreover, some defaults of the plotting functions are only suitable for PM data. Hence, the functions should be called slightly distinctly.

Besides these slight restrictions, which are illustrated with examples below, non-PM data can be analysed with **opm** almost like PM data.

2. Preparation

As usual, **opm** must be loaded before any analysis can begin:

```
R> if ("package:opm" %in% search())
         detach("package:opm", unload = TRUE)
R> library("opm")
```

3. Growth-curve data input

3.1. User-entered data frames

In the following we will use the growth-measurements data set from Vaas, Marheine, Sikorski, Göker, and Schumacher (2013) as exemplar. These data have been entered by hand and then input into R with one of the functions for reading Comma-Separated Values (CSV), yielding a data frame, which comes with **opm**:

```
R> data("potato")
R> head(potato)
```

```
Genotype Treatment Replicate Time FM DM
1 07-08-1 0.16M NaCl
                             1
                                  2 597 44
2 07-08-1 0.16M NaCl
                             2
                                  2 550 40
3 07-08-1 0.16M NaCl
                             3
                                  2 633 48
4 07-08-1 0.16M NaCl
                             4
                                  2 490 31
  07-08-1 0.16M NaCl
                             5
                                  2 617 47
6 07-08-1 0.16M NaCl
                                  4 585 55
                             1
```

For details on this data set, enter ?potato at the R prompt. The measurements are in "long" format and must be reshaped using the eponymous function into "wide" format. We do this separately for the Dry Mass (DM) and Fresh Mass (FM) measurements within the data set:

"long" format means, that each measurement is stored in a separate record with one entry per line (see above). Thus for each data point the entries in "Genotype", "Treatment" and "Time" have to be repeated, resulting in a data frame with dimensions of 540 rows in 6 columns.

With the reshape it is possible to rearrange the data set in a form, where the columns "Genotype", "Treatment" and "Replicate" are kept and columns "Time" and either "FM", or "DM" respectively, are merged resulting in 9 columns representing the measurement times (see below the first six rows of object potato.fm).

```
R> head(potato.fm)
```

```

                                                               1853
                                                                     2335
                                                                           2564
                                                                                  2426
46 07-08-1 0.32M NaCl
                                1
                                   395
                                        551
                                              392
                                                   342
                                                         322
                                                                322
                                                                      368
                                                                            336
                                                                                   274
```

Thus the dimension of the data object dwindled to 60 rows in 12 columns.

Now the data are in the right arrangement for the next step, the conversion into OPMX or MOPMX objects.

It is possible to first register the plate and then convert the data into an OPM object.

R>

The main function for converting user-defined data frames to OPMX or MOPMX objects is opmx, which can directly be applied to the objects created in the last step. This works because the "horizontal" input format of opmx corresponds to the "wide" format of reshape.

```
R> potato.fm <- opmx(potato.fm, position = c("Genotype", "Replicate"),
    well = "Treatment", prefix = "FM.",
    full.name = c(fm = "Growth experiment, fresh mass"))
R> potato.dm <- opmx(potato.dm, position = c("Genotype", "Replicate"),
    well = "Treatment", prefix = "DM.",
    full.name = c(dm = "Growth experiment, dry mass"))</pre>
```

The data frame contains all substrate information (in the "Treatment" column). Hence, **opm** registers the mapping from well coordinates to substrate names on the fly. The plate type must be provided, however. As it is not within the data frame, the short name of the plate type is taken from the full.name argument, whose main purpose is to enter the full, descriptive name of the plate type. "Genotype" and "Replicate" go to the metadata of the resulting object and together identify each plate. In the case of PM data, this is done using the position of the plate within the OmniLog® reader. Thus the relevant argument here is position, which must be supplied unless there is a column of that name. The prefix argument helps identifying the columns with measurements over time.

The registered plate type can be queried as follows:

```
R> plate_type(TRUE) # shows all existing user-defined plates
[1] "CUSTOM:DM" "CUSTOM:FM"
R> listing(wells(plate = c("CUSTOM:FM", "CUSTOM:DM")))
CUSTOM:FM:
    Growth experiment, fresh mass
    A01: 0.16M NaCl
    A02: 0.32M NaCl
    A03: 0.5M Sorbitol
```

```
A04: Control
CUSTOM:DM:
- Growth experiment, dry mass
- A01: 0.16M NaCl
A02: 0.32M NaCl
A03: 0.5M Sorbitol
A04: Control
```

Note the prefix "CUSTOM:", which is used to distinguish user-defined plate type from those that come with **opm**. Please keep in mind, that the definition of plate types is only available in the current R session. The definitions will be lost, when the session is terminated. Saving and/or loading of a session can be managed by the functionality provided by **session** (Warnes. 2012).

The object resulting from listing can be output with to_yaml or saveRDS for externally storing plate types in files.

With the potato.dm and potato.fm objects the user can now follow the work flow as it is envisaged for processing of usual PM data. Please continue in Section 4 and following for plotting and statistical analysis of the estimated curve parameters.

3.2. Direct registration of plate types

An example input file comes along with **opm**, providing growth curve data which were derived from an growth challenging experiment with two *Escherichia coli* strains (Deutsche Sammlung von Mikroorganismen (DSM) 18039 = K12 and the type strain DSM 30083^T) on increasing Glucose concentrations. Each strain-Glucose-concentration combination was repeated twice on the plate. Thus, it will first be shown, how to prepare a plate map, register it as a new plate type and import the data with subsequently conversion of the data into an OPMX or MOPMX object. Afterwards it will be shown how to use the split function in order to split the objects to provide objects representing the repetitions.

3.2.1. Set up a plate map and register plate types

Provided by register_plate, opm brings several options for setting up a user defined plate layout. This function works with both customised PM plates run, as well as plates of other well design and formats used for measurement of for example growth in a conventional plate reader.

For small set ups it might be feasible to type the substrate allocation manually into a character string, as it is done in the following.

```
R> register_plate(growth = c(A01 = "negative control #1", A02 = "10mM Glucose #1", A03 = "20mM Glucose #1", A04 = "50mM Glucose #1", A05 = "100mM Glucose #1", A06 = "200mM Glucose #1", B01 = "negative control #2", B02 = "10mM Glucose #2", B03 = "20mM Glucose #2", B04 = "50mM Glucose #2", B05 = "100mM Glucose #2", B06 = "200mM Glucose #2", C01 = "negative control #3", C02 = "10mM Glucose #3", C03 = "20mM Glucose #3", C04 = "50mM Glucose #3", C05 = "100mM Glucose #3", C06 = "200mM Glucose #3", D01 = "negative control #4", D02 = "10mM Glucose #4",
```

However, this procedure is error prone and not efficient when dealing with sets containing more than a few wells. Alternatively, a user-designed plate can also be registered with a plate map given as matrix. The matrix then directly represents the allocation of the used substrates on the plate.

First, the matrix for the plate map has to be stated as follows.

The next step is to register the layout as a new plate type. Here it is named "growth".

```
R> growth.reg <- register_plate(growth = growth)
R> # listing(wells(plate = "CUSTOM:GROWTH"))
```

Alternatively, the input for register_plate can also be a data frame.

```
R> growth.dat <- as.data.frame(growth)
R> growth.dat.reg <- register_plate(growth.dat = growth.dat)
R> # listing(wells(plate = "CUSTOM:GROWTH-DAT"))
```

3.3. Input of TECAN data

Here we will use an exemplar that comes with **opm** as input data file:

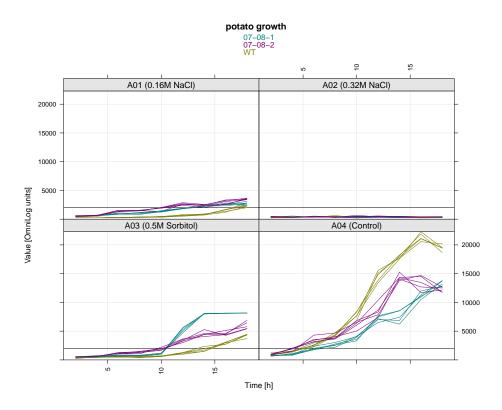

Figure 1: here some caption about the plot

This format is not particularly useful within R but can be converted using the "rectangular" mode of opmx.

```
R> # rectangular input, as it comes from the 'tecan' object
R> (y <- opmx(tecan, "rectangular", plate.type = "growth", position = 1,</pre>
       interval = 1))
```
