Working with substrate information in opm

Lea A.I. Vaas Leibniz Institute DSMZ Johannes Sikorski Leibniz Institute DSMZ Markus Göker Leibniz Institute DSMZ

Abstract

This is the substrate-information tutorial of **opm** in the version of October 7, 2013.

Keywords: Cell Lines, Metadata, Microbiology, Respiration Kinetics, Pathway, KEGG, pathview.

1. Introduction

A detailed description of the OmniLog® Phenotype MicroArray (PM) system, its measuring procedure and data characteristics are found in the vignette "opm: An R Package for Analysing OmniLog® Phenotype MicroArray Data" (called "main tutorial" in the following). The description of the methods below presupposes that the user is familiar with the usage of opm and has studied the main tutorial as well as the entries of the opm manual relevant to her or his research. Especially the concept and structure of the different object-classes should be made clear before starting with this tutorial.

In addition to visual inspection or statistical comparative analyses of Phenotype Microarray data, as described in the main manual, users might be interested in specific information on the substrates used in PM assays. The **opm** package contains a large variety of additional data on PM substrates. Beside methods for assessing these information directly, this tutorial introduces strategies for visualization of the measured PM results by mapping on pathwaymaps and introduces analysis methods for modelling and identification of informative and less informative substrates.

2. Preparation

Before starting, install the package **pathview** from Bioconductor (http://bioconductor.org/packages/2.12/bioc/html/pathview.html) and load it together with the **opm** package, into an R session. Please note, that it is important to load **pathview** before **opm**, since otherwise some functions are not visible and the package does not work properly. In this vignette this is catched by the if-construct.

```
R> suppressPackageStartupMessages(library("pathview"))
R> if ("package:opm" %in% search())
         detach("package:opm")
R> library("opm")
R> data(vaas_et_al, package = "opmdata")
```

3. Available plate information

Currently substrate layouts of various plates are available within **opm**. An overview about the plate types available in the respective version of **opm** is obtained by entering

```
R> plate_type(full = TRUE)
```

The resulting vector of names does not only include OmniLog® plates; see the manual and the main tutorial for further details. Using other values for full, or additional arguments, distinct spelling variants of the plate names can be obtained.

4. Accessing substrate information

The **opm** package contains a number of functions suitable for accessing precomputed information on the substrates within certain wells and entire plates. In the manual and help pages these functions are explained within the family "naming-functions" with according cross-references. One usually would start a search by determining the exact spelling of an internally used name with find_substrate():

```
R> substrates <- find_substrate(c("Glutamine", "Glutamic acid"))
R> substrates
```

The results is a list (of the \$3 class "substrate_match") containing character vectors with the results for each query name as values. Surprisingly, nothing was found for "Glutamic acid" but several values for "Glutamine". The default search argument is "exact", which is exact (case-sensitive) matching of substrings of the names. One might want to use "glob" searching mode:

```
R> substrates <- find_substrate(c("L-Glutamine", "L-Glutamic acid"), "glob") R> substrates
```

But with so-called wildcards, i.e. "*" for zero to many and "?" for a single arbitrary character the search is more flexible:

```
R> substrates <- find_substrate(c("*L-Glutamine", "*L-Glutamic acid"), "glob")  
R> substrates
```

This fetches all terms that end in either query character string, and does so case-insensitively. Advanced users can apply the much more powerful "regex" and "approx" search modes; see the manual for details, entry ?find_substrate.

Note that **opm** appends a concentration (or just repetition) indicator as a number after a hash sign ("#") to the substrate names wherever necessary. Thus a wildcard at the end of a name might often by the most useful search pattern.

Once the internally used names (which are not guaranteed to be stable between distinct **opm** releases) have been found, information on the substrates can be queried such as their occurrences and positions on plates:

```
R> positions <- find_positions(substrates)
R> positions
```

This yields a nested list containing two-column matrices with plate names in the first and well coordinates in the second column. References to external data resources for each substrate name can be obtained using substrate_info():

```
R> subst.info <- substrate_info(substrates)
R> subst.info
```

By default this yields CAS numbers (http://www.cas.org/content/chemical-substances/faqs), but MeSH names (useful for conducting PubMed queries; see http://www.ncbi.nlm.nih.gov/mesh/) (Coletti and Bleich 2001), ChEBI IDs (Hastings, de Matos, Dekker, Ennis, Harsha, Kale, Muthukrishnan, Owen, Turner, Williams, and Steinbeck 2013), KEGG compound IDs, KEGG drug IDs (Kanehisa, Goto, Furumichi, Tanabe, and Hirakawa 2010) and MetaCyc IDs (Caspi, Altman, Dreher, Fulcher, Subhraveti, Keseler, Kothari, Krummenacker, Latendresse, Mueller, Ong, Paley, Pujar, Shearer, Travers, Weerasinghe, Zhang, and Karp 2012) IDs have also been collected for the majority of the substrates. Using the "browse" argument, full URLs can be created and optionally also directly opened in the default web browser. Using the "download" argument, if KEGG drug or compound IDs have been selected, these can be downloaded from the KEGG server if the KEGGREST is available and converted into customized objects. It is possible to nicely display all available information at once:

```
R> subst.info <- substrate_info(substrates, "all")
R> subst.info
```

Another use of substrate_info() is to convert substrate names to lower case but protecting name components such as abbreviations or chemical symbols. See the manual for further details, help page ?substrate_info.

5. Visualisation by integration in pathway maps

In conjunction with other packages, it is possible to visualize PM results directly in preexisting pathway maps as, for example, from the KEGG database. Those maps are essentially manually drawn pathway maps representing the currently available knowledge about genes, substrates and their connection in pathways. Depending on availability of genome and gene-annotation information within KEGG about a certain organism, individual maps are allocateable (Kanehisa *et al.* 2010).

The mapping itself is simply the introduction of PM-measurement data as colour-coding of nodes (here, representing the substrates) into those maps, as it can be done similarly with several other types of OMICS-data. For details, please see the description on the KEGG-homepage: (http://www.genome.jp/kegg/).

Here we will use the function pathview from the package of same name (Luo and Brouwer 2013). This function downloads the user-defined pathway map and subsequently maps and renders the given PM-data into it. Please note, that it has to be loaded *before* loading package **opm** into an R session.

5.1. suitable input-data

The workflow starts with either an OPMX object containing the agregated values, or the result from an opm_mcp analysis. The first step in both cases is to bring the PM-results in a suitable format, which is a named vector created by annotated.

```
R> # here provide the annotated vector from vaas_1
R> xx <- annotated(vaas_1)
R> head(xx)

<NA> C00721 C00208 C01083 C00185 C08240
123.4558 248.1809 284.0994 269.7548 180.7536 287.7959
```

The resulting vector basically contains the numeric values (selected parameter estimates or opm_mcp results, as explained below) as well as an annotation of the according substrates. With the what-argument, passed as eponymous argument to substrate_info, the user can indicate which kind of information should be used for the annotation. annotated works directly on OPMX-objects containing aggregated data for single plates or bundles of plates. However, please note, that the output allows for only one value per substrate. When applying annotated to a set of plates, make sure, that only one experimental group is comprised, since the resulting values are averages per well over all plates. Using the output-argument, one is able to choose which parameter should be adressed, for example AUC instead of maximum height:

```
R> y <- annotated(vaas_1, output = param_names()[4])
R> head(y)

<NA> C00721 C00208 C01083 C00185 C08240
8918.137 18391.590 21960.080 18531.180 11831.150 19254.160
```

Further options allow for indication of categorical (different) and for the opm_glht method, binary outcomes (smaller, larger or equal).

But visualization of the results of an <code>opm_mcp</code> analysis is also possible, which offers more (statistically interesting) opportunities for making sense of the PM data in the context of pathways. The results from an <code>opm_mcp</code> procedure are treated with <code>annotated</code> as shown before with an <code>OPMX</code> object:

```
R> x <- opm_mcp(vaas_4[, , 1:15], output = "mcp", model = \sim Well, linfct = c(\simDunnett.A05\sim = 1), full = FALSE)
```

However, this method only makes sense, if each coefficient estimated by opm_mcp can be linked to a single substrate. This is usually only possible for the "Dunnett" and "Pairs" type of contrast if applied to the wells.

95% family-wise confidence level

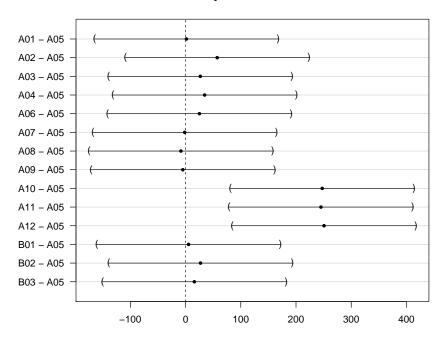

Figure 1: Point estimates and 95% confidence intervals in a manually defined comparison of group means for a specifically selected set of wells (A01 to B03) from the vaas_4 exemplar object. In this procedure each well is compared against A05. The picture was obtained by running opm_mcp() and then the plotting function for the resulting opm_glht-object. See the main tutorial for details.

With this example, the options allowing for categorical output of annotated will be illustrated. Obviously, only three comparisons exhibit a statistically significant difference, namely the comparisons A10 - A05, A11 - A05 and A12 - A05, all in the way that A05 is smaller than A10, A11 and A12, respectively.

Using the output-argument users are able to get various categorical results beside simple numerical output of the respective point estimator. The options upwards and downwards result classifications in three categories (FALSE, NA, or TRUE), giving an indication, if the CI is located in the positive or negative range with resulting NA, if zero is included and thus no decission possible. The options different, smaller, larger and equal work similarly, but use only the two categories TRUE and FALSE.

```
R> anno.nu <- annotated(x, output = "numeric")
R> anno.up <- annotated(x, output = "upwards")
R> anno.do <- annotated(x, output = "downwards")
R> anno.di <- annotated(x, output = "different")
R> anno.eq <- annotated(x, output = "equal")
R> anno.sm <- annotated(x, output = "smaller")
R> anno.la <- annotated(x, output = "larger")</pre>
```

A comprehensive overview of the results with the above stated example is facilitated by bundling the results of all possible options into one dataframe:

```
R> annotab <- data.frame(Comparison = rownames(confint(x)$confint),</pre>
     numeric = anno.nu, upwards = anno.up, downward = anno.do,
     different = anno.di, equal = anno.eq, smaller = anno.sm, larger = anno.la)
R> annotab
   Comparison
                 numeric upwards downward different equal smaller larger

                               NA
                                        NA
                                                       TRUE
                                                              FALSE
                                                                      FALSE
               27.079437
   B02 - A05
                               NA
                                        NA
                                                FALSE
                                                       TRUE
13
                                                              FALSE
                                                                      FALSE.
                                                FALSE
   B03 - A05
               15.870312
                               NA
                                        NΑ
                                                      TRUE
                                                              FALSE FALSE
```

Using the argument how = "value" a numeric matrix containing the chosen computed values together with their abundance in pathway maps can be investigated.

5.2. Visualisation in pathway-maps using pathview

Basically, pathview maps and renders pathway graphs (from KEGG) and integrates additional data provided from other sources, mainly experimental data from various OMICS-approaches. Here the functions serves to integrate and visualize PM data provided by

annotated. The user has to specify the pathway, provide the PM-data and all necessary steps (download of pathway graph data, parsing of data file, maping user's data to the pathway, and rendering of pathway graph with the mapped data) are executed automatically by pathview.

Generally, a pathway map is described as "[...]a molecular interaction/reaction network diagram represented in terms of the KEGG Orthology (KO) groups [...]"(see http://www.genome.jp/kegg/kegg3a.html for further details). KEGG contains a collection of different types of pathway maps, precisely identifiable by the combination of 2-4 letter code and 5 digit number.

The letter prefixes have the following meanings:

```
map - Reference pathway

ko - Reference pathway (KO)

ec - Reference pathway (EC)

rn - Reference pathway (Reaction)

org - Organism-specific pathway map
```

Only the first reference pathway map is manually drawn; all other maps are computationally generated. pathview allows only for usage of KEGG orthology (the ko-maps) or species specific letter code (see http://www.genome.jp/kegg/catalog/org_list.html for an upto-date list of organisms with complete genome information in KEGG). The ko-maps contain the manually defined ortholog groups (ko entries) for all proteins and functional RNAs that correspond to KEGG pathway nodes, BRITE hierarchy nodes, and KEGG module nodes, whereas the species specific maps contain

Before you start with this section, please make sure, that you have installed the **pathview** package including all its dependencies from Bioconductor (http://bioconductor.org/packages/2.12/bioc/html/pathview.html).

To provide more convenient functionality for mapping PM-data on KEGG-pathway maps, we wrote a wrapper for the pathview-function. This wrapper provides mainly fine tuned settings for the convenient application of pathview on PM-data. All graphics below are produced using this wrapper, however, the user is free to use the original pathview-function with the respectively changed arguments.

```
R> opm_path <- function(cpd.data, high = list(gene = "green4", cpd = "magenta4"),
    low = list(gene = "white", cpd = "white"),
    mid = list(gene = "lightsteelblue1", cpd = "lightsteelblue1"),
    pathway.id = "00052", species = "ko", out.suffix = "non-native",
    kegg.native = F, key.pos = "bottomright", afactor = 1000,
    limit = list(gene = 2, cpd = 400), bins = list(gene = 0.5, cpd = 20),
    both.dirs = list(gene = FALSE, cpd = FALSE), cex = 0.7,
    sign.pos = "bottomleft", cpd.lab.offset = 0, same.layer = F, rank.dir = "TB",
    pdf.size = c(14,10), gene.data = NULL, ...) {
        pathview(gene.data = gene.data, cpd.data = cpd.data, na.col = "grey",</pre>
```

```
low = low,
             mid = mid,
             high = high,
             pathway.id = pathway.id,
             species = species,
             out.suffix = out.suffix,

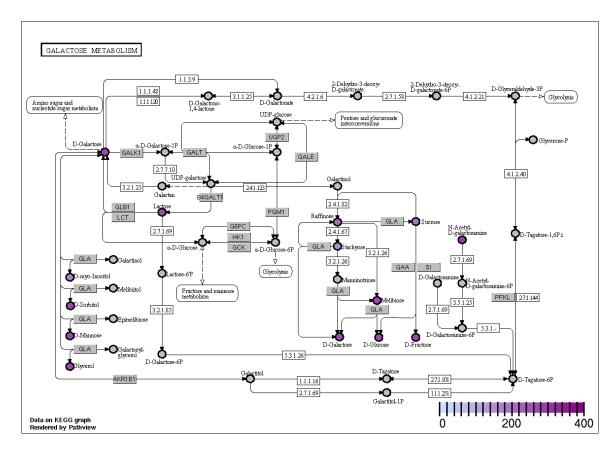

Figure 4: Map of galactose metabolisms for humans in native KEGG representation.

6. Model-building approach using random forest

Using the argument how= "value" a numeric matrix containing the chosen computed values together with their abundance in pathway maps can be investigated. In analogy to the download argument of substrate_info the information are converted into a numeric matrix. Please note, that this option is not available for all values of what and requires additional libraries. See substrate_info for details.

```
R> anno.glht.mat <- annotated(x, how = "values")
R> anno.glht.mat
```

	Value	map00052	map00500	map01100	map02010	map02060	map04973
Negative Control	1.6	NA	NA	NA	NA	NA	NA
Dextrin	57.3	0	1	1	0	0	0

pH 5	250.8	NA	NA	NA	NA	NA		NA
D-Raffinose	5.4	1	0	0	0	0		0
a-D-Lactose	27.1	1	0	1	1	1		1
D-Melibiose	15.9	1	0	0	0	0		0
	Carboh	ydrates Disa	accharides	Oligos	accharides	exact_	mass	
Negative Control		NA	NA		NA		NA	
Dextrin		0	0		0		NA	
D-Maltose		1	1		1		342	
D-Trehalose		1	1		1		342	
b-Gentiobiose		1	1		1		342	
Sucrose		1	1		1		342	
Turanose		1	1		1		342	
Stachyose		0	0		0		666	
Positive Control		NA	NA		NA		NA	
pH 6		NA	NA		NA		NA	
pH 5		NA	NA		NA		NA	
D-Raffinose		0	0		0		504	
a-D-Lactose		1	1		1		342	
D-Melibiose		1	1		1		342	

The obtained information about the pathway certain substrates are involved in can be used to determine manually which pathways are actually of interest or can serve as input for model-building procedures as, for example, random forest approaches, which is demonstrated below.

7. Acknowledgements

The integration of missing OmniLog® substrates into ChEBI by the ChEBI staff is gratefully acknowledged.
